GORENSTEINNES OF SEGRE-VERONESE  
GRADED ALGEBRAS

by

Serban Bărcănescu

0. Abstract

The characterization of the Gorenstein property for the Veronese algebras was done by V.Brînzănescu [5] and independently by A.Matsuoka [7], in a pure algebraic manner.

The general case of the Segre-Veronese singularities was treated by L.Bădescu [1] and by L.Bădescu and N.Manolache [2], the characterization of the Gorenstein property of these singularities, in terms of their numerical character, being obtained geometrically, using Serre's duality, in the natural context of the Segre-Veronese embeddings.

The present paper contains an alternate proof of the same result, based upon two facts: the characterization of the Gorenstein property for G-algebras in terms of their Hilbert functions, given in [8] by R.Stanley and the analytic expression of the Hadamard product of two rational functions of one complex variable, given in [4] by L.Bieberbach.

1. G-Algebras

All the rings involved are commutative, with unit element.

Let  $k$  be a field. By a "G-algebra" over  $k$  we mean a noetherian,  $\mathbb{N}$ -graded ring;  $R = \bigoplus_{n \geq 0} R_n$ , with  $R_0 = k$ .

Such a structure satisfies:

( $\forall$ )  $n \geq 0$ ,  $\dim_k R_n$  is finite.

The numerical function:  $\chi_R : n \mapsto \dim_k R_n$ , called "the Hilbert function" of  $R$ , is polynomial i.e. there is a polynomial  $Q(t) \in \mathbb{Z}[t]$

and there is an integer  $n_0 > 0$ , such that:

$$n \geq n_0 \Rightarrow \chi_R(n) = Q(n).$$

The least of such integers  $n_0$  is called " the regularity index " of  $R$  (cf. [9]) and is denoted by  $r(R)$ .

The dimension of  $R$  is uniquely determined by  $\chi_R$ , namely:

$$\dim R = 1 + \deg \chi_R = 1 + \deg Q(t).$$

The generating series of the sequence  $(\chi_R(n))$  i.e. the formal power series:  $H_R(t) = \sum_{n \geq 0} \chi_R(n) \cdot t^n \in \mathbb{Z}[[t]]$  is called " the Hilbert-Poincaré series " of  $R$ .

As  $\chi_R$  is polynomial, it results that  $H_R$  is rational, i.e. defines an element of  $\mathbb{Q}(t)$ .

If  $\{x_1, \dots, x_d\}$  is a set of homogeneous generators for the  $k$ -algebra structure of  $R$ , of degrees respectively  $m_1, \dots, m_d$ , then there is a canonical surjective  $k$ -homomorphism:

$$k[X_1, \dots, X_d] \longrightarrow R$$

sending  $X_j$  into  $x_j$  ( $j=1, \dots, d$ ). Hilbert's theorem on syzygies says that  $R$  has finite homological dimension over  $k[X_1, \dots, X_d]$ , i.e.  $R$  has a finite free resolution over  $k[X_1, \dots, X_d]$  (of length  $\leq d$ ), showing that:

$$H_R(t) = P_R(t) \cdot \prod_{j=1}^d (1 - t^{m_j})^{-1}, \text{ where } P_R(t) \text{ is a polynomial with}$$

integral coefficients.

When  $m_1=m_2=\dots=m_d=1$  i.e. when  $R = k[R_1]$  the G-algebra  $R$  is called "standard" and, in this case,

$$H_R(t) = P_R(t)/(1-t)^d, \text{ where } P_R(1) \neq 0 \text{ and}$$

$d = \text{Krull dim } R$ , as the dimension of  $R$  is the order of the pole:  $t=1$  of the rational function  $H_R$ . We shall constantly make use of this normalized form of the Hilbert function of a standard G-algebra.

The Gorensteinness of G-algebras is characterized in the following:

1.1. Theorem (R. Stanley, [8])

Let  $R$  be a Cohen-Macaulay domain and a G-algebra. Then  $R$  is Gorenstein if and only if its Hilbert-Poincaré series, considered as a rational function, satisfies the following functional relation:

$$H_R(1/t) = (-1)^{\dim R} \cdot t^{q(R)} \cdot H_R(t)$$

where  $q(R)$  is an integer uniquely determined by  $R$ .

1.2. Remark

If, in the Theorem 1.1, the G-algebra  $R$  is standard, then, looking at the normalized form of  $H_R$ , we see that Gorensteinness in this case means that the polynomial  $P_R$  is reciprocal, i.e. satisfies

$$P_R(1/t) = t^{-\deg P_R} \cdot P_R(t).$$

Moreover, in this case one obtains:

$q(R) = \dim R - \deg P_R$  (see also [8]).

## 2. Veronese G-algebras

Let  $k$  be a field and  $r, s$  be two positive integers.

### 2.1. Definition

The "Veronese  $k$ -algebra of type  $(r; s)$ " is the  $k$ -subalgebra of the polynomial algebra  $k[T_1, \dots, T_r]$ , generated by all the monomials of degree  $s$ , i.e. by:

$$\left\{ T_1^{i_1} \cdot T_2^{i_2} \cdot \dots \cdot T_r^{i_r} \mid i_1 + i_2 + \dots + i_r = s \text{ in } \mathbb{Z}_+ \right\}.$$

This algebra will be denoted by  $V_{rs}$ , when the field  $k$  is fixed. According to this definition, it is easy to see that  $V_{rs}$  is a standard  $G$ -algebra and a domain of Krull dimension  $r$ . The graded structure of  $V_{rs} = \bigoplus_{n \geq 0} V_{rs}(n)$  is given by

$$(\forall) n \geq 0, \dim_k V_{rs}(n) = \binom{r+ns-1}{r-1}.$$

$V_{rs}$  is always Cohen-Macaulay: indeed,  $\{T_1^s, \dots, T_r^s\}$  is a system of parameters and a regular sequence in  $V_{rs}$  (another argument for the Cohen-Macaulayness of  $V_{rs}$  is based on a theorem of Hochster [6], asserting that a monoidal algebra  $k[M]$  over a field  $k$  is Cohen-Macaulay if the monoid  $M$  is normal; in our case the monoid of all the monomials contained in  $V_{rs}$  is obviously normal).

Let  $H_{rs}(t) = P_{rs}(t)/(1-t)^r$  be the (normalized) Hilbert-Poincaré series of  $V_{rs}$ , written in its rational form, and let  $H_r(t) = (1-t)^{-r}$  be the Hilbert-Poincaré series of the ambient polynomial ring  $k[T_1, \dots, T_r]$ . Directly from 2.1 we see that  $H_{rs}$  is obtained from  $H_r$  by selecting

the terms from  $s$  to  $s''$ .

The following lemma yields a general procedure for such a selection

## 2.2. Lemma

Let  $f(t)$  be a rational function from  $\mathcal{C}(t)$  and let:

$$f(t) = \sum_{n \geq 0} a_n \cdot t^n$$

be its development near the origin in  $\mathcal{C}$ .

Then, if  $f_s(t) =: \sum_{n \geq 0} a_{ns} \cdot t^n$ , then the following relation holds in the Puiseux power series field over  $\mathcal{C}$ :

$$1/s \left[ \sum_{j=1}^s f(z_j t^{1/s}) \right] = f_s(t)$$

where  $z_1, \dots, z_s$  are the  $s$ -roots of the unity in  $\mathcal{C}$ .

### Proof.

For any  $s$  indeterminates  $X_1, \dots, X_s$  we denote by  $\sigma_k(X_1, \dots, X_s)$  the  $k$ -th elementary symmetric function, on the  $X_i$ 's, i.e.:

$$\sigma_k(X_1, \dots, X_s) = \sum_{1 \leq i_1 < i_2 < \dots < i_k \leq s} X_{i_1} X_{i_2} \dots X_{i_k}.$$

For every positive integer  $m$ , let  $p_m(X_1, \dots, X_s)$  be the sum of the  $m$ -th powers of the  $X_i$ 's, i.e.:

$$p_m(X_1, \dots, X_s) = X_1^m + \dots + X_s^m.$$

Then the  $p_m$ 's may be determined through the  $\sigma_k$ 's, because of Newton's formulas (holding in  $\mathbb{Z}[X_1, \dots, X_s]$  (cf. [3])):

(a)  $1 \leq k \leq s$ :

$$p_k - p_{k-1} \sigma_1 + p_{k-2} \sigma_2 - \dots + (-1)^{k-1} p_1 \sigma_{k-1} + (-1)^k \cdot k \cdot \sigma_k = 0$$

(b)  $s < k$

$$p_k - p_{k-1} \sigma_1 + p_{k-2} \sigma_2 - \dots + (-1)^{s-1} p_{k-s+1} \sigma_{s-1} + (-1)^s p_{k-s} \sigma_s = 0$$

Specializing:

$X_1 = z_1, \dots, X_s = z_s$  ( $z_j$  being the  $s$ -roots of the unity in  $\mathbb{C}$ ),  
and making use of the Vieté's relations for  $Z^s - 1 = 0$ , we obtain

$$\sigma_k(z_1, \dots, z_s) = 0, \quad 1 \leq k \leq s-1$$

$$\sigma_s(z_1, \dots, z_s) = (-1)^{s+1}$$

and thus:

$$p_m(z_1, \dots, z_s) = \begin{cases} 0, & \text{if } m \not\equiv 0 \pmod{s} \\ s, & \text{if } m \equiv 0 \pmod{s}. \end{cases}$$

Then, in the conditions of the enounce:

$$\sum_{j=1}^s f(z_j t) = \sum_{n \geq 0} a_n p_n(z_1, \dots, z_s) t^n,$$

which immediately gives the desired relation, if we look at the above values of the  $p_n$ 's.

q.e.d.

Now we are in position to prove the following:

### 2.3. Theorem

The Veronese algebra  $V_{rs}$  of type  $(r; s)$  over a field  $k$  is Gorenstein

if and only if  $r \equiv 0 \pmod{s}$ .

Proof.

According to 1.1 and 1.2 we need only to show that (in the above notations):  $P_{rs}$  is reciprocal iff  $r \equiv 0 \pmod{s}$ .

Or, applying lemma 2.2 to  $H_r(t) = (1-t)^{-r} = \sum_{n \geq 0} \binom{r+n-1}{r-1} t^n$ , one obtains:

$$(*) \quad P_{rs}(t) = 1/s \cdot \sum_{j=1}^s \left( \sum_{i=0}^{s-1} z_j^i \cdot t^{i/s} \right)^r$$

This relation actually holds in  $\mathbb{Z}[t]$ , i.e. the right-side member in (\*) is a polynomial with integral coefficients. To see this we use the multinomial formula, expanding every term in the right-side member of (\*) and making use of the possible values of  $p_n(z_1, \dots, z_s)$  we obtain:

$$(**) \quad P_{rs}(t) = \sum_{a=0}^b C_a \cdot t^a, \text{ where } b = [r(s-1)/s] \text{ (integer part) and}$$

the coefficients  $C_a$  are, for every  $a$ :

$$C_a = \sum_{(i_1, \dots, i_s) \in S_a} r! / i_1! \dots i_s!$$

the index sets  $S_a$  being:

$$S_a = \left\{ (i_1, \dots, i_s) \in \mathbb{Z}_+^s / i_1 + \dots + i_s = r \text{ and } i_2 + 2i_3 + \dots + (s-1)i_s = a \cdot s \right\}$$

Suppose  $P_{rs}$  is reciprocal as polynomial from  $\mathbb{Z}[t]$ .

This means that the coefficients  $C_a$  in (\*\*) are two by two equal when going from the extremities to the middle of  $P_{rs}$ .

In particular:

$$C_0 = C_b.$$

Or, it is immediate that  $C_0 = 1$ . Then, looking at (\*\*) and taking into account all the possible values for the  $p_n$ 's, we see that  $C_b = 1$  iff  $r(s-1) \equiv 0 \pmod{s} \Leftrightarrow r \equiv 0 \pmod{s}$ , obtaining the necessity of the condition in theorem 2.3.

For the sufficiency, let us suppose that  $r = m \cdot s$ , with  $m \in \mathbb{N}$ .

Then, in the above notations,  $b = \left\lfloor r(s-1)/s \right\rfloor = m \cdot (s-1)$ .

Let  $S = \bigcup_{a=0}^b S_a$  be the total index set in (\*\*). In every coefficient  $C_a$ , every term:  $r!/i_1! \dots i_s!$  is a positive integer.

Bearing this in mind, let us look at the function:

$g: S \rightarrow S$ , given by:

$$(\forall) (i_1, \dots, i_s) \in S, g((i_1, i_2, \dots, i_{s-1}, i_s)) = (i_s, i_{s-1}, \dots, i_2, i_1)$$

So defined,  $g$  establishes a bijection between  $S_a$  and  $S_{b-a}$ , for any  $a \in \{0, 1, \dots, b\}$ , and immediately given:

$$C_a = C_{b-a}$$

because every term:  $r!/i_1! \dots i_s!$  of  $C_a$  differs from the corresponding one in  $C_{b-a}$  only by the permutation  $g$  on the indices  $(i_1, \dots, i_s)$ .

Or, this shows that  $P_{rs}$  is reciprocal in this case and ends the proof of the theorem.

q.e.d.

### 3. Segre-Veronese G-algebras

Let  $R = \bigoplus_{n \geq 0} R_n$  and  $S = \bigoplus_{n \geq 0} S_n$  be two G-algebras over the same

field  $k$ .

The " Segre product " of  $R$  and  $S$  is, by definition, the  $G$ -algebra over  $k$ :

$$RoS = \bigoplus_{n \geq 0} R_n \otimes_k S_n,$$

which is a domain of standard type if  $R$  and  $S$  are such.

Cohen-Macaulayness is preserved by the Segre product iff  $([9])$ :

$$r(R) \leq \min \{n/S_n \neq 0\} \text{ and } r(S) \leq \min \{n/R_n \neq 0\}.$$

The Hilbert function of  $RoS$  is obviously:

$$\chi_{RoS} = \chi_R \cdot \chi_S, \text{ showing that:}$$

$$\begin{aligned} \dim RoS &= 1 + \deg \chi_{RoS} = 1 + \deg \chi_R \cdot \chi_S = 1 + \deg \chi_R + \deg \chi_S = \\ &= 1 + (\dim R - 1) + (\dim S - 1) = \dim R + \dim S - 1. \end{aligned}$$

Finally, the Hilbert-Poincaré series of  $RoS$  is:

$$H_{RoS} = \sum_{n \geq 0} \chi_R(n) \cdot \chi_S(n) \cdot t^n, \text{ i.e. } H_{RoS} \text{ is the Hadamard product}$$

of  $H_R$  and  $H_S$ .

We shall use the following integral representation for the Hadamard product of two rational functions  $f$  and  $g$  of complex argument  $t$  (cf. [4]):

$$(1) \quad (f \circ g)(t) = \frac{1}{2\pi i} \int_C f(1/z) g(tz) dz/z$$

where, if  $r_f$  and  $r_g$  are the convergence radii of  $f$  and  $g$ , then the convergence radius  $r_{fg}$  of  $f \circ g$  verifies:  $r_{fg} \leq \min \{r_f, r_g\}$

and the integration road in (1) is the circle:

$$C : |z| = \xi, \text{ with } 1/r_f < \xi < r_g/|t|.$$

### 3.1. Remark

The Hadamard product  $f \circ g$  is a commutative multiplication on  $\mathcal{C}[[t]]$ . In order to see the commutativity on the integral representation (1), one must change the variable:  $z \rightarrow 1/u$  and then one must invert the orientation of the integration road  $C$ .

### 3.2. Proposition

Let  $R$  and  $S$  be two Gorenstein domains and  $G$ -algebras over the same field  $k$ . Then their Segre product,  $R \circ S$  is Gorenstein, if (in the notations of part 1):

$$\underline{q(R) = q(S)}.$$

#### Proof.

In the notations of part 1, we have:

$$2\pi i (H_R \circ H_S)(t) = \int_C H_R(1/z) H_S(tz) dz/z, \text{ where}$$

$$C : |z| = \xi, \text{ with:}$$

$1/r_R < \xi < r_S/|t|$ ,  $r_R$  and  $r_S$  being the convergence radii of  $H_R$  and  $H_S$  respectively.

We make use of theorem 1.1. Then:

$$2\pi i (H_R \circ H_S)(1/t) = \int_{C'} H_R(1/z) H_S(z/t) dz/z$$

where now  $C' : |z| = \xi'$ ,  $1/r_R < \xi' < |t| \cdot r_S$ .

Because  $R$  and  $S$  are Gorenstein, we see, from theorem 1.1, that:

$$\begin{aligned} 2\pi i (H_R \circ H_S)(1/t) &= \int_{C^1} (-1)^{\dim R} \cdot z^{q(R)} H_R(z) \cdot (-1)^{\dim S} \cdot \\ &\quad \cdot t^{q(S)} z^{-q(S)} H_S(t/z) dz/z = \\ &= (-1)^{\dim R + \dim S} \cdot t^{q(S)} \int_{C^1} z^{q(R) - q(S)} \cdot H_R(z) H_S(t/z) dz/z. \end{aligned}$$

Now, we change the variable:  $z \rightarrow 1/u$ , and, making use of 3.1, we obtain:

$$(2) \quad 2\pi i (H_{R \circ S})(1/t) = (-1)^{\dim R \circ S} t^{q(S)} \int_{\Gamma} u^m H_R(1/u) H_S(tu) du/u$$

where:  $\Gamma: |u| = \lambda$ ,  $1/r_R < \lambda < r_S / |t|$  and  $m = q(R) - q(S)$ .

The integrand in the right-side member of (2) differs from the suited one, as given in (1), only by the multiplicative factor:  $u^m$ . Thus, if  $m=0$ , one obtains the conclusion of Proposition 3.2 from the theorem 1.1

q.e.d.

### 3.3. Corollary

In the above assumptions and notations:

$$\underline{q(R \circ S) = q(R) = q(S)}.$$

#### Proof.

Obvious, if we look at the proof of 3.2 and at 1.1.

Now, let  $\gamma = (r_1, \dots, r_n; s_1, \dots, s_n)$  be a sequence of  $2n$  positive integers.

In the notations of part 2 we give the following:

### 3.4. Definition

The "Segre-Veronese algebra of numerical character  $(r_1, \dots, r_n; s_1, \dots, s_n)$ " over a field  $k$ , is the Segre product of the Veronese algebras over  $k$ :  $V_{r_1 s_1}, \dots, V_{r_n s_n}$ . Keeping fixed the field  $k$ , we denote simply by  $V_{\gamma}$  the Segre-Veronese algebra of numerical character  $\gamma = (r_1, \dots, r_n; s_1, \dots, s_n)$ . It is easy to see that  $V_{\gamma}$  is a domain of Krull dimension  $r_1 + \dots + r_n - n + 1$ , naturally embedded in the polynomial  $k$ -algebra in  $r_1 + \dots + r_n$  variables.  $V_{\gamma}$  is a standard  $G$ -algebra, its graded structure:

$$V_{\gamma} = \bigoplus_{n \geq 0} V_{\gamma}(n)$$

being given by:

$$(\forall) n \geq 0, \dim_k V_{\gamma}(n) = \prod_{j=1}^n \binom{r_j + n s_j - 1}{r_j - 1}.$$

$V$  is Cohen-Macaulay, as one can see using either the above quoted characterization of the Cohen-Macaulayness of the Segre product of two  $G$ -algebras (cf. [9]) or the theorem of Hochster [6], as the normality of the monoides of monomials is preserved by the Segre product.

Now, we shall prove the main result of this paper, namely:

### 3.5. Theorem

The Segre-Veronese algebra of numerical character  $(r_1, \dots, r_n; s_1, \dots, s_n)$  over a field  $k$ , is Gorenstein if and only if there is an integer  $q$ , such that:

$$\underline{r_1/s_1 = r_2/s_2 = \dots = r_n/s_n = q}$$

Proof.

First, using 1.2 and 2.3, we see that, for any Veronese algebra  $V_{rs}$  over a field  $k$ , the Gorensteinness of  $V_{rs}$  implies that:

$$q(V_{rs}) = \dim V_{rs} - \deg P_{rs} = r - r(s-1)/s = r/s.$$

Then, using an induction on  $n$ , we see that all we have to prove is, because of 3.2 and 3.3, that the sufficient condition in 3.2 is also necessary in order to insure the Gorensteinness of the Segre product  $R \circ S$ , in the case when  $R$  and  $S$  are two Veronese algebras:  $R = V_{rs}$ ,  $S = V_{r's'}$ .

Looking at (2) in the proof of 3.2, we must show that (in the notations of part 2):

$$(3) \quad \int_{\Gamma} (u^m - 1) \cdot H_{rs}(1/u) H_{r's'}(tu) du/u = 0 \text{ if and only } m=0.$$

(Here  $\Gamma: |u| = \xi$ , with  $1 < \xi < 1/|t|$ , because  $H_{rs}$  and  $H_{r's'}$  both have the convergence radius equal to 1).

According to the results of part 2, we know that:

$$H_{rs}(t) = P_{rs}(t)/(1-t)^r \text{ and } H_{r's'}(t) = P_{r's'}(t)/(1-t)^{r'}$$

with  $P_{rs}$  and  $P_{r's'}$  reciprocal polynomials in  $\mathbb{Z}[t]$ , of degrees respectively:  $r(s-1)/s$  and  $r'(s'-1)/s'$  ( $V_{rs}$  and  $V_{r's'}$  being Gorenstein) and satisfying:

$$P_{rs}(1) \neq 0 \text{ and } P_{r's'}(1) \neq 0 \text{ (cf. part 1).}$$

Then (3) becomes:

$$(4) \int_{\Gamma} (1-u^m)/(1-u)^r u^{r/s-1} \cdot P_{rs}(u) \cdot P_{r's'}(tu)/(1-tu)^{r'} du = 0$$

with the same  $\Gamma$ .

Or, in the domain bounded by the circle  $\Gamma$ , the integrand in (4) has a unique pole, namely  $u=1$ . Thus, the integral in (4) equals the residue in  $u=1$  of the rational function:

$$h(u) = (1-u^m)/(1-u)^r \cdot p(u), \text{ where:}$$

$$p(u) = u^{r/s-1} \cdot P_{rs}(u) \cdot P_{r's'}(tu)/(1-tu)^{r'}.$$

Or, one directly sees that  $p(u)$  is analytic near  $u=1$  and more, that  $p(1) \neq 0$ . Then, except for the trivial case  $r=1$ , a direct computation shows that the residue in  $u=1$  of  $h(u)$  is non zero when  $m \neq 0$ , implying (3) and ending the proof of the theorem.
