in very special situations. Indeed, to handle the set of isomorphism classes of objects of a given kind, the first thing one generally tries is to decompose it into a (generally infinite) disjoint union of "quotients" of certain algebraic schemes by certain "algebraic" equivalence relations. But even if such a decomposition into "quotients" is available, the corresponding "quotients" generally do not exist as algebraic schemes (or as algebraic spaces); this is the case for instance with the polarized nonsingular projective varieties where the ruled ones spoil the picture [17]. On the other hand it may happen that no such decomposition into "quotients" is available at all: this seems to be the case (at least apriori) with: a) finitely presented algebras, b) complete local algebras, c) linear algebraic groups, a.s.o.

To remedy the lack of global moduli spaces there are at least two changes of viewpoint—which can be made: first one can adopt a "local" viewpoint on moduli (in the sense of Kodaira-Spencer, Schlessinger,...); secondly one can adopt a "birational" viewpoint on moduli (as suggested by work of Matsusaka, Shimura, Koizumi [6] [17] [24]).

It is the birational viewpoint which we follow in this paper. It consists associating to each isomorphism class ξ of objects of a given kind a field $k(\xi)$ which should play the role

of "residue field at ξ " on a global moduli space. In $\left[17\right]$ Matsusaka proved the existence of the fields $k(\xi)$ for nonsingular polarized projective varieties and called them "fields of moduli"; his strategy was geometric, via "quotients", hence does not seem to apply to cases a), b), c) above.

The aim of this paper is to introduce a new method by which we prove the existence of the fields $k(\xi)$ for large classes of objects (possibly equipped with certain additional structures) belonging to classes a), b), c) above. For precise statements, see Section 2. Our method is of purely algebraic nature; it is of independent interest since it is based on killing nonabelian cocycles of certain nonprofinite groups .

Rather than speaking about "fields of moduli" we will speak in our paper about "course representability" of certain functors of fields; as we shall see "course representability" is "essentially equivalent" to the existence of "fields of moduli" (cf. assertion (5) in Theorem (1.5)).

The paper is divided into two parts. In part I we prove an abstract criterion of "coorse representability" for functors of fields (assertion (6) in Theorem (1.5)), we consider some basic examples of such functors and state our main Theorem (2.10) which asserts that most our functors are "coorsely regresentable" in characteristic zero. In part II we use nonabelian cohomology to split algebras over skew group algebras in order to check that our functors satisfy the axioms appearing in our criterion of coorse representability.

As a concluding remark note that there are remarkable cases where the "local moduli theory" is trivial whereas the "birational moduli theory" is not (e.g. the case of smooth affine varieties, which have no nontrivial infinitesimal deformations but lots of global deformations "depending effectively on a certain number of moduli"). On the other hand there are cases

when there is no satisfactory "local moduli theory" whereas there is a satisfactory "birational moduli theory" (e.g. the case of nonnecessary isolated singularities). Both cases above will be discussed in our paper.

PART 1: FUNCTORS OF FIELDS

1. Abstract theory

(1.1) Let $B^a \subset B = B^e$ be categories (here "c" means "subcategory") and let $C: B \longrightarrow S$ (= category of sets) be a contravariant functor. For any object $X \subset B^e$ define the functor $h_X: B \longrightarrow S$ by $h_X(Y) = Hom_{B^e}(Y, X)$ for all $Y \subset B$.

We say that an object $X \in B^e$ codrsely represents C if there is a morphism $\varphi: C \longrightarrow h_{\chi}$ satisfying the following properties

 (m_1) $\forall (Y) : C(Y) \longrightarrow h_X(Y)$ is a bijection for all $Y \in B^a$

Clearly (m_2) uniquely determines X up to a "canonical" isomorphism in B^e .

The prototype for the definition above is Mumford's concept of course moduli space (in that case the objects of B are locally noetherian schemes, those of B are also schemes or more generally algebraic spaces while the objects of B are the spectra of algebraically closed fields).

(1.2) From now on we shall fix a ground field k; all objects and maps will be "over k". Throughout the paper we assume that B is the dual of the category of fields, B^a is the full subcategory of B whose objects are the algebraically closed fields while B^e is the category which we shall now descri-

be. Given a set X, by a birational structure on it we mean a family of fields $\{k(x); x \in X\}$; a set together with a birational structure on it will be called a birational set. By a morphism between two birational sets X and Y we mean a map $f: X \to Y$ together with field homomorphisms $f_{x}^{*}: k(f(x)) \to k(x)$ for all $x \in X$. Birational sets form a category which we denote by B^{e} . B is viewed as a subcategory of B^{e} by letting a field K be identified with the birational set $X = \{x\}$, k(x) = K. A birational set X is called of finitely generated type if k(x) is a finitely generated extension of k for all $x \in X$. A birational set X coursely representing a functor $C: B \to S$ will be called a birational moduli set for C.

Intuitively the field k(x) should be viewed as the "residue field" of X at x. Moreover note that if $X \in B^e$ and $K \in B$ then

$$h_{X}(K) = \{(x,u); x \in X, u : k(x) \rightarrow K \text{ a field homomorphism} \}$$

so h_{χ} is a "birational analogue" of the "functor of points" of a scheme in algebraic geometry.

First we fix some notations. If K/K is a field extension, $g(K/K_0)$ will denote the group of K automorphisms of K and we write g(K) instead of g(K/k). If g = g(K) is a subgroup then K^g will denote the subfield of K of elements fixed by g; g is called Galois-closed if $g = g(K/K^g)$.

Now given a functor $C: \mathbb{R} \longrightarrow S$, K a field and $f \in C(K)$

we say that a subfield K_O of K is a field of definition for ξ if $\xi \in \operatorname{Im}(C(K_O) \longrightarrow C(K))$. Denote by $D(\xi) = D(\xi, C)$ the set of those subfields of K which are fields of definition for ξ . Moreover note that g(K) acts on C(K) on the right by the formula $\xi^{\sigma} = C(\sigma^{-1})(\xi) \text{ for } \sigma \in g(K), \ \xi \in C(K); \text{ let}$

$$g(\xi,C) = g(\xi) = \{ \sigma \in g(K); \xi = \xi \}$$

be the isotropy of ξ under this action. Finally define

 $K_{\xi}^{=}$ intersection of all members of $D(\xi)$ $K_{\xi}^{\infty} = \text{intersection of all perfect members of } D(\xi)$ $K^{\xi}_{=} = K^{g(\xi)}.$

If K is algebraically closed then some easy remarks are in order (cf. [16] [24]):

- 1) If $K_0 \in D(\xi)$ then $g(K/K_0) \subset g(\xi)$, in particular we have $K^{\xi} \subset K_{\xi}^{\infty}$.
- 2) $g(\xi)$ acts on $D(\xi)$ hence globally invariates K_{ξ}^{∞} ; so if $g(\xi)$ is Galois-closed and K/K_{ξ}^{∞} is not algebraic then K_{ξ}^{∞}/K^{ξ} is an algebraic normal extension.
- 3) It is not reasonable to expect that $K_{\xi} \in D(\xi)$; this fails in very nice situations (e.g. k=Q, C(K)=set of isomorphism classes of non-singular projective curves over K [24]).
- (1.4) A field will be called universal if it is algebraically closed and has uncountable transcendence degree over k. We denote by B^U the full subcategory of B consisting of universal fields and by B^W the full subcategory of B consisting of those fields which are countably generated over κ ; so $B^U = \bullet$

separably closed in K.

Let $C:B\longrightarrow S$ be a functor, $\xi\in C(K)$ and consider the following properties:

- (g_1) , $g(\xi)$ is Galois-closed
- (g_2) $K_{\xi}^{\circ} = K^{\xi}$
- (g_3) K_{ξ}^{∞}/K_{ξ} is purely insenarable
- (d_1) $D(\xi)$ contains an algebraic extension of K^{ξ}
- (d_2) $D(\xi)$ contains a regular extension of K^{ξ} belonging to B^{ω}
 - (d_3) $D(\xi)$ contains a finitely generated extension of k.

A functor $C:B \to S$ will be said to have property (g_i) or (d_i) for some $1 \le i \le 3$ if for all $K \in B^U$ and all $\xi \in C(K)$, ξ has the corresponding property. Consider also the following properties which make sense for any functor $C:B \to S$.

- (w) For any K&B we have $C(K)=\lim_{\longrightarrow} C(E)$ where E runs through the set of all subfields of K belonging to B.
- (s) For any extension K'/K, K, $K' \in B^a$ the map $C(K) \longrightarrow C(K')$ is injective.
 - (m) C has a birational moduli set of finitely generated type.

Note that $(g_1)+(g_2)+(g_3)$ implies the fact that \S has a "field of moduli" in Koizumi's sense [16] while (g_1) says that \S has a "field of moduli" in Shimura's sense [24]. Note also that in our applications property (s) will be essentially a "specialisation" property.

It will be convenient to consider the following variations of (d_1) and (d_2) (making sense for any functor $C: E \longrightarrow S$):

- $(\widehat{S_1}) \text{ For all } \underline{K\in B}^U \text{ and all } \underline{\xi}\in C(K) \text{ there exists an extension}$ $\widehat{K}/K \text{ such that } D(\widehat{\underline{\xi}}) \text{ contains. an algebraic extension of } K$ $(\text{where } \widehat{\underline{\xi}} \text{ is the image of } \underline{\xi} \text{ via } C(K) \longrightarrow C(\widehat{K})).$
- $(\stackrel{f}{\circ}_2) \text{ For all KEB}^a \cap B^w \text{ and all } \xi \in C(K) \text{ there exists an extension } \tilde{K}/K \text{ with } \tilde{K} \in B^w \text{ such that } D(\stackrel{f}{\xi}) \text{ contains a regular extension } of K^{\stackrel{f}{\xi}}.$

The following result summarizes the relevant implications between the above properties (the last implication being the key one in our approach):

- .(1.5) THEOREM. For a functor $C:B \longrightarrow S$ the following hold:
- 1) $(s) + (\delta_1) \Longrightarrow (d_1)$
- 2) $(s)+(d_1)+(d_3) \Longrightarrow (g_1)$
- 3) (w) + (s) + (δ_1) + (δ_2) \Longrightarrow (d_2)
- 4) $(\omega) + (g_1) + (d_2) \Longrightarrow (g_2)$
- 5) $(w)+(s)+(d_1)+(d_3)+(g_1)+(g_2)+(g_3) \iff (w)+(d_3)+(m)$
- 6) $(w)+(s)+(\delta_1)+(\delta_2)+(d_3) \Longrightarrow (m)$ if char (k)=0.
- Remarks. a) Implication 6) is a formal consequence of 1)-5)
 - b) Implication 4) is contained in [16]
- c) The equivalence 5) is a characterisation of course representability (under the hypothesis $(\omega)+(d_3)$).
 - d) Implication 2) plays a key role in our approach,
 - Proof. 1) is standard and we omit proof.
- 2) For any subfield L of a field $K \in B^U$ and for any $\xi \in C(K)$ but $g(\xi/L) = g(\xi) \land g(K/L)$.

Claim 1: If Les then c(\$/L) is Galois-closed.

Indeed, by $(d_1) \ \xi = C(i) (\xi^0)$ where j is the natural inclusion of K_0 , the algebraic closure of $K_0^{(\xi/L)}$, into K and $\xi^0 = C(K_0)$. Now $K_0 \in \mathbb{B}^U$ hence by (d_3) there is a finite falois extension K_1 of $K_0^{(\xi/L)}$ contained in K_0 with $K_1 \in D(\xi)$. We have $g(K/K_1) = g(\xi/L) = g(K/K_0^{(\xi/L)})$. Upon letting H to be the image of $g(\xi/L)$ under the projection $g(K/K_0^{(\xi/L)}) \to g(K_1/K_0^{(\xi/L)})$ we have by Galois theory that $H = g(K_1/(K_1)^H)$ hence $g(\xi/L) = g(K/(K_1)^H)$ which easily implies our claim.

Now let's prove that $g(\xi) = g(K/K^{q(\xi)})$. We will make a "reduction to the uncountable case". Let k' be a purely transcendental extension of k having uncountable transcendence degree over k, let $K' = Q(K \otimes_k k')$ be the quotient field of $K \otimes_k k'$, F an algebraic closure of K' and ξ_F be the image of ξ via $C(K) \longrightarrow C(F)$. By our Claim 1 we have $g(\xi_F/k') = g(F/F^{g(\xi_F/k')})$. Now take $G = g(K/K^{g(\xi)})$, let G = g(K'/k') be its unique extension and let $G = g(K/K^{g(\xi)})$ be any extension of G'.

Claim 2:
$$\tilde{\sigma} \in g(F/F^{g(\frac{\xi}{5}_F/k^4)})$$

Assuming this for a moment we get that $\widetilde{\sigma_{\mathcal{E}}} \varsigma(\xi_{\mathsf{F}}/\mathsf{k}^{\mathsf{f}})$ so $\xi_{\mathsf{F}} = (\xi_{\mathsf{F}})^{\widetilde{\mathsf{F}}} = (\xi_{\mathsf{F}})^{\widetilde{\mathsf{F}}} = (\xi_{\mathsf{F}})^{\widetilde{\mathsf{F}}}$ and we conclude by (s) that $\xi = \xi_{\mathsf{F}}$ i.e. that $\sigma \in \mathfrak{q}(\xi)$. So 2) will be proved if we prove claim 2. Let

$$g = \left\{ \widetilde{\tau} \in g(F/k^*) : \widetilde{\tau}(K) = K, \widetilde{\tau} \mid_{K} \in g(\xi) \right\}$$

Clearly there is a surjective homomorphism $g \rightarrow g'$ where

$$9' = \{ \tau' = \tau \otimes 1 \in g(K'/k'); \tau \in g(\xi) \}$$

$$F^{g(\xi_{F}/K')} \subset F^{g} = (F^{g(F/K')})^{g} = (K')^{g} = (K')^{g'} = Q(K^{g(\xi)} \otimes k')$$

where the the index "i" means "nerfect closure" and the last equality is a consequence of a remark made in [27] nn.405-406. Now our Claim 2 follows because $\widetilde{\sigma}$ is the identity on $\mathbb{Q}(\mathsf{K}^{\mathfrak{g}}(\xi)) \otimes_{\mathsf{K}} \mathsf{K}')$.

- 3) Let $K \in B^U$, $\xi \in C(K)$ and let K_0 be the algebraic closure of K^{ξ} in K. By (ω) , $K_0 \in B^{\omega}$. By (d_1) there exists some $\xi_0 \in C(K_0)$ whose image in C(K) is ξ . Applying (\mathcal{C}_2) to K_0 and ξ of there is an extension of K/K_0 such that $K \in B^{\omega}$ and $D(\xi)$ contains a regular extension of $K_0^{\xi_0}$ (ξ image of ξ_0 in C(K)). Now there exists a K_0 -isomorphism U of K onto a subfield K_1 of K. With ξ_1 image of ξ in $C(K_1)$ clearly we have that $D(\xi_1)$ contains a regular extension of $K_0^{\xi_0}$ contained in K_1 . We shall be done if we prove that $K_0^{\xi_0} = K^{\xi_0}$. But this is easily checked through property (s).
- 4) Let $x \in K \setminus K$; it is sufficient to find a perfect field $E \in D(\xi)$ with $x \notin E$. By (d_2) there exists $F \in D(\xi) \cap B^{\omega}$ with F a reqular extension of K^{ξ} . Let F_1 be the perfect closure of F in K; since K^{ξ} is perfect, K^{ξ} is algebraically closed in F_1 . So one can find $\sigma \in g(K/K^{\xi})$ such that $\sigma \times \notin F_1$. By (g_1) , $\sigma \in g(\xi)$ hence $x \notin \sigma^{-1}F_1 \in D(\xi)$.
- 5) To prove implication from left to right we need the following definition. Given a subcategory B^O of B a morphism $\varphi^O: C|_{B^O} \longrightarrow h_{X|_{B^O}}$ is said to have property (m_1) if it induces isomorphisms on all objectis of $B^O \cap B^O$. Then we proceed in several steps:

Step 1. Let $K \in B^U$ and denote by B^K the subcategory of B whose objects are the subfields of K and whose morphisms are defined by

Hom
$$_{BK}(E,F)=\int_{U\in Hom_{B}}(E,F);$$
 u can be extended to some $\widetilde{u}\in g(K)$

Define a birational set as follows. Put X=C(K)/g(K), let $s:X\to C(K)$ be any section of the projection $p:C(K)\to X$ and put $k(x)=K_{s(x)}$ for all $x\in X$ (k(x)/k is finitely generated by (d_3)). We construct a morphism $y^K:C|_{BK}\to h_X|_{BK}$ having property (m_1) as follows. For any subfield E of K and any $\xi_E\in C(E)$ let $\xi=\xi_K$ be the image of ξ_E in C(K); we have $s(p(\xi))=\xi^{\sigma}$ for some $\sigma\in g(K)$ and we put $\varphi^K(E)(\xi_E)=(x_\xi,u_\xi)$ where $x_\xi=p(\xi)$ and $u_\xi:k(x_\xi)\to E$ is defined as the composition

$$k(x_{\xi}) = K_{s(p(\xi))} \xrightarrow{\sigma} K_{\xi} = E$$

Note that by $(g_2)+(g_3)$ does not depend on the choice of σ . Moreover if E is almebraically closed $\varphi^K(E)$ is injective due to properties $(s)+(g_1)+(g_2)+(g_3)$ and surjective due to properties $(\omega)+(d_1)+(g_2)+(g_3)$.

Step 2. Let K and φ^K be as in Step 1. We can construct a functor $\beta: \beta^\omega \to \beta^K$ with the property that for any $E \in \beta^\omega$ we have an isomorphism $\beta_E: E \curvearrowright \beta(E)$ in B and for each arrow $u: E \to E'$ in B we have $\beta(u) \circ \beta_E = \beta_E \circ u$. Define a morphism $\varphi: C \mid \beta^\omega \to h_X \mid \beta^\omega$ as follows for any $E \in \beta^\omega$ let $\varphi^\omega(E)$ be defined by the commutative diagram:

$$C(E) \xrightarrow{\varphi^{\omega}(E)} h_{\chi}(E)$$

$$C(\beta_{E}) \downarrow h_{\chi}(\beta_{E})$$

$$C(\beta(E)) \xrightarrow{\varphi^{\kappa}(\beta(E))} h_{\chi}(\beta(E))$$

Clearly φ^{w} has (m_{1}) .

Step 3. Using axiom (w) φ^w can be extended to a morphism $\varphi: C \to h_X$ which will still have property (m_1) .

Step 4. We claim that Υ has also property (m_2) . To check this take any morphism $\Upsilon':C\to h_X$, choose KEB^U and consider the g(K)-equivariant maps of sets $\varphi(K):C(K) \xrightarrow{\sim} h_X(K)$, $\varphi'(K)=C(K) \xrightarrow{\sim} h_X(K)$. Taking orbits we get maps $\widehat{\varphi}:C(K)/g(K) \xrightarrow{\sim} h_X(K)/g(K) \xrightarrow{\sim} h_X(K)/g(K) \xrightarrow{\sim} h_X(K)/g(K)$ and define $f:X\to X'$ by $f=\pi\circ\widehat{\varphi}'\circ\widehat{\varphi}^{-1}$ where $\pi:h_X(K)/g(K)\to X'$ is the natural projection. Moreover if $\varphi(K)(\xi)=(x_{\xi},u_{\xi})$ and $\varphi'(K)(\xi)=(x_{\xi},u_{\xi})$ for $\xi\in C(K)$ then by functoriality of φ' we have $u_{\xi}(K(x_{\xi}))=K_{\xi}$ while by the very construction of X we have $u_{\xi}(K(x_{\xi}))=K_{\xi}$ consequently we get field homomorphisms $f^*:K(f(x))\to K(x)$ hence a morphism $f:X\to X'$ unique with the property $h_{\xi}\circ \varphi= \varphi'$.

The other implication in 5) is proved along the same lines; it will not be used in the sequel and we omit details.

As already noted 6) follows from the preceeding implications.

(1.6) The following general situation will often occur in what follows. Let's make the following definition: a morphism $C \longrightarrow C$ between functors from B to S will be called a full embedding if the map $C'(K) \longrightarrow C(K)$ is injective for all $K \in B$ and

$$c(K) \cap c(j)^{-1}(c'(K')) = c'(K)$$

for any field extension j:K -> K.

Now if $C' \longrightarrow C$ is a full embedding and $\xi \in C(K)$ for some $K \in B$ then clearly $D(\xi,C) = D(\xi,C')$, $g(\xi,C) = g(\xi,C')$. Consequent-

ly if C has one of the properties (a_i) , (d_i) , (d_i) , (ω) , (s) the same holds for C'.

Suppose $C:B\longrightarrow S$ is a functor. An element $\xi\in C(K)$ is called bounded if there exists a field extension K'/K, a subfield K_O of K' finitely generated over K and an element $\xi_O \in C(K_O)$ such that ξ and ξ_O have the same image in C(K'). For any $K \in B$ let $C^b(K)$ denote the set of all bounded elements in C(K). Then $K \mapsto C^b(K)$ defines a functor $C^b:B\longrightarrow S$ fully embedded in C.

2. Some remarkable functors. Main result.

- which we are going to consider are the "moduli functors" associated to suitable fibred categories over B. More precisely let C be a fibred category over B; by this we mean that for any K \in B we are given a category C $_{\rm K}$, for any field homomorphism u:K \rightarrow K' we are given a "base channe" functor C $_{\rm U}:{\rm C}_{\rm K} \rightarrow {\rm C}_{\rm K}$ and for any pair of field homomorphisms K $\stackrel{\cup}{\rightarrow}$ K' we are given a functorial isomorphism C $_{\rm U}$, v:C $_{\rm V}$ o C $_{\rm U}$ \rightarrow C $_{\rm VU}$, all these data being subject to same natural compatibility conditions [10]. Given C as above one can define the "moduli functor" (still denoted by C) from B to S by the formula C (K) = C $_{\rm K}$ /iso (= set of isomorphism classes of objects in C $_{\rm K}$). If A \in C $_{\rm K}$ and $\xi_{\rm A}$ is its image in C (K) we put D (A) = D ($\xi_{\rm A}$) and g (A) = g ($\xi_{\rm A}$).
- (2.2) The functors PAL, PAL, HAL. By a K-algebra (K a field) we understand either an associative unitary (not necessarily commutative) K-algebra or a Lie K-algebra. By a polarization on a K-algebra A we mean a finite dimensional K-linear subspace P of A which generates A as a K-algebra. By a polarized K-algebra.

bra we mean a K-alnebra A with a given polarization P_A on it. A polarized K-algebra is of course finitely generated; it is called finitely presented (respectively homogeneous) if the kernel of $K \not P_A \rightarrow A$ is a finitely generated (respectively finitely generated and homogeneous) ideal of $K \not P_A \rightarrow A$ = free (associative or Lie) K-algebra on P_A . The polarized (respectively polarized finitely presented, respectively homogeneous) K-algebras form a category which we call PAL_K (respectively PAL_K , HAL_K); a morphism is by definition a K-algebra map $f:A \rightarrow B$ such that $f(P_A) \subset P_B$. For any field homomorphism $K \rightarrow K'$ we define base change functors $PAL_K \rightarrow PAL_K$ by $A \mapsto A' = K' \otimes_K A$, $P_{A'} = K' \otimes_K P_A$ (and analogously for $PAL_K \cap PAL_K$); the resulting fibred category and moduli functor are denoted by PAL (respectively $PAL_K \cap PAL_K \cap$

Finite dimensional K-algebras A have a natural structure of polarized finitely presented K-algebras via P_A =A. Another remarkable example of algebras which carry a natural polarization will be given below (cf. (2.4) and (2.8)).

(2.3) The functors CLA, CLS. A complete local K-alnebra will always be assumed commutative, noetherian, with residue field K. Denote by CLA_K the category of complete local K-alnebras. Define the base change functors $CLA_K \rightarrow CLA_K$, by $A \mapsto K' \otimes_K A$ ($\stackrel{\triangle}{\otimes} =$ completed tensor product) and denote by CLA the resulting fibred category and moduli functor. As we shall see below the functor CLA^b of bounded complete local algebras (cf. (1.7)) will prove itself to have good moduli theoretic properties. Note for instance that any $A \in CLA_K$ which is algebraisable in the sense of [1] is bounded. It seems to be an open problem whether any complete local algebra is bounded (cf. the end of [2]).

For technical reasons it is convenient to consider also a "relative" situation. Namely, for a fixed intener N>1 let $K[X] = K[X], \ldots, X_N[X]$ be the power series alcebra over K and let CLS_K be

the category of complete local K-algebras A equipped with a local algebra homomorphism $K[X] \to A$ (the morphisms in CLS_K being assumed to agree with the maps $K[X] \to A$). These CLS_K define a fibred category and a moduli functor CLS.

- (2.4) The functors AFF, AFF⁺. By an affine K-algebra we mean a finitely generated, commutative, geometrically reduced Kalgebra. Denote by AFF , the category of affine K-algebras (which is antiequivalent to the category of affine K-varieties) and by AFF the resulting fibred category and moduli functor. We say that $A \in AFF_K$ has non-negative Kodaira dimension (compare with [21]) if it is geometrically integral and there exists a smooth completion X of V_{reg} (=regular locus of Y=Spec(A)) such that $S_m(X, D) :=$ $=H^{O}(X,W, {\textstyle \bigcirc}^{m}((m-1)D))\neq 0$ for some $m\geqslant 1$ (where D is the reduced divisor X $^{\text{V}}_{\text{reg}}$ assumed to have normal crossings and $\overset{\omega}{_{\text{X}}}$ is the canonical bundle on X). If char(k)=0 then by [4][21] S_m(X,|p) (viewed as a subspace of the space of regular m-uple n-forms on V where n=dim(A)) does not depend on the choice of the completion of V_{reg} ; if K= \mathbb{C} , $S_m(X,D)$ can be interpreted as the space of regular m-uple n-forms on V_{req} with finite "volume". Denote by AFF_K^+ the full subcategory of AFF of all algebras having a non-negative Kodaira dimension and by AFF⁺ the resulting fibred category and moduli functor.
- (2.5) The functor COH. For any field K let COH_K denote the category of finitely generated K[X]- modules $(X=(X_1,\ldots,X_N))$. Define base change functors $COH_K \to COH_K$, by $E \mapsto E \otimes_{K[X]} K[X] = -K' \otimes_K E$. We get a fibred category and a moduli functor COH.
- (2.6) The functor LFS, Fix a complete local k-algebra R with prof(R) \geqslant 2 and for any field K let LFS(K) be the set of .

isomorphism classes of locally free coherent sheaves on the punctured spectrum $Y_K = \operatorname{Spec}(R_K) \setminus \left\{ M(R_K) \right\}$ where $R_K = K \otimes_k R$ and $M(R_K)$ is the maximal ideal of R_K . We defined a functor LFS:B \longrightarrow S.

(2.7) The functors AHA, AHA^P, AHA^r. Let AHA_K denote the category of affine Hopf K-algebras (which is anti-equivalent to the category of linear algebraic K-groups [12]). With obvious base change functors we get a fibred category and hence a moduli functor AHA.

A reductive algebraic K-group P (char(K)=0) will be called pure if: Aut(P)/Int(P) is finite. If K is algebraically closed P is pure if and only if its center has dimension ≤ 1 ([12] p.218 and [7], p.409). An affine Hopf K-algebra A(Char(K)==0) will be called pure if, upon letting L=Spec(A), U=R_U(L)==unipotent radical of L we have that L/U is pure (L/U exists and is reductive by [12] pp.80 and 117). Let AHAP be the full subcategory of AHAR of pure Hopf algebras and AHAP the resulting fibred category and moduli functor.

Suppose $A \in AHA_K$, char(K)=0. By a rigidification on A (or on L=Spec(A)) we mean the giving of the isomorphism class V of a faithful representation V of L/U (where once again $U=R_U(L)$). Since L/U is reductive the set of all possible rigidiffications on a given A is a "discrete" set (i.e. it does not increase by base change $K \longrightarrow K'$, K, $K' \in B^a$). By a rigidified affine Hopf-K-algebra we mean a pair consisting of an object $A \in AHA_K$ and a rigidification V on it. Rigidified affine Hopf K-algebras form a groupoid which we call AHA_K^r ; we obtain a fibred groupoid and a moduli functor AHA^r .

(2,8) PROPOSITION. There exist full embeddings:

a) AFF \propto PAL f PAL. HAL PAL

b) LFS
$$\xrightarrow{\beta}$$
 COH $\xrightarrow{\delta}$ CLS \xrightarrow{b} CLS \xrightarrow{b}

where for α , β , β we assume char(k)=0.

Proof. The only non-obvious arrows are a, B, 8.

To construct \propto the key point is that any $A \in AFF_K^+$ has a canonical polarization P_A . It is constructed as follows. Let V=Spec(A), (X,D) a smooth normal crossing completion of V_{reg} and let m > 1 be the smallest integer such that $S_m(X,D) \neq 0$. Then consider for each integer n > 1 the K-linear subspace of A:

$$A_{n} = \left\{ f \in A; f \cdot \beta_{1} \otimes \dots \otimes \beta_{n} \in S_{mn} (X, D) \text{ for all } \beta_{1}, \dots, \beta_{n} \in S_{m} (X, D) \right\}$$

Clearly $\dim_K A_n \stackrel{\frown}{=} \infty$ for all $n\geqslant 1$ and $A=\bigcup_{n\geqslant 1} A_n$. Let N be the smallest integer such that A_N generates A as a K-algebra and define a polarization $P_A=A_N$. Note that $:= \cup:A \longrightarrow A'$ is a K-isomorphism and $V'=\operatorname{Spec}(A')$, (X',D') a smooth normal crossing completion of (V') reg then by $A=\bigcup_{n\geqslant 1} A_n$ the map $A=\bigcup_{n\geqslant 1} A_n$. Let N be nationally a smooth normal crossing completion of $A=\bigcup_{n\geqslant 1} A_n$ is a K-isomorphism of $A=\bigcup_{n\geqslant 1} A_n$. Let N be nationally a smooth normal crossing completion of $A=\bigcup_{n\geqslant 1} A_n$ is a K-isomorphism of $A=\bigcup_{n\geqslant 1} A_n$. Let N be nationally a smooth normal crossing completion of $A=\bigcup_{n\geqslant 1} A_n$ is a K-isomorphism of

To construct β write R=k[X]/I and send a bounded locally free sheaf F on Y_K into the K[X]- module $F'=H^O(Y_K, F)$. By a theorem of Grothendieck [10]F' is finitely generated. Now β is a full embedding by the yoqa in [10].

Finally, to construct \mathcal{T} we proceed as follows. To any K[X]-module E which is bounded and finitely generated we associate the local complete K-algebra $K[X] \oplus E$ $(E^2=0)$ equipped

lind ruly L

with the obvious inclusion map $K[X] \to K[X] \oplus E$; this will be an element of $CLS^b(K)$. To check that X is a full embedding one has to prove that if L/K is a field extension, A is a bounded complete local K[X] - algebra and $L \otimes_K A \cong L[X] \oplus E$ is an isomorphism of L[X] - algebras (with E a finitely generated bounded L[X] - module) then $A \cong K[X] \oplus E_0$ for some bounded finitely generated K[X] - module E_0 . It is sufficient to show that $(\min(A))^2 = 0$ and the natural map $u: K[X] \longrightarrow A_{red} = A/\min(A)$ is an isomorphism. The condition on nil is clear while for the second condition the formula $(L \otimes_K A)_{red} = L \otimes_K (A_{red})$ (which holds by separability of L/K) shows that $1 \otimes u: L \otimes_K K[X] \to L \otimes_K (A_{red})$ is an isomorphism which implies that so is u (look at the associated graded rings).

(2.9) It is an easy exercise to check that the functors PAL^f . AHA. AHA r . AFF have properties (ω) (d_3) (s). Clearly CLS has property (ω) . Moreover CLS^b has property (d_3) use the fact that if a system of algebraic equations with coefficients in a universal field K involving at most countably many unknowns has a solution in a field extension of K, then it has a solution in K; we would like to stress the following technical point: here the universality of K is essential and this justifies both our definition of property (d_3) and the somewhat boring "reduction to the uncountable case" in the proof of 2) in (1.5), Finally note that by a result of Seidenberg [22] CLA has property (s); same arguments as in [22] show that in fact CLS has (s).

The main effect of our theory will be the following:

(2.10) THEOREM. Suppose char(k)=0. Then the functors a) HAL, AFF $^+$, PAL f ; b) CLA b , COH b , LFS b ; c)AHA p , AHA r have property (m).

In view of 6) in Theorem (1.5) together (1.6), (2.8), (2.9) the statement above will be proved if we prove the following

(2.11) THEOREM. The functors PAL and CLS satisfy (\mathcal{S}_1) and (\mathcal{S}_2) . Moreover if char(k)=0, AHA satisfies (\mathcal{S}_1) , AHAP satisfies (\mathcal{S}_2) and AHAT satisfies (\mathcal{S}_1) and (\mathcal{S}_2) .

As a Corollary of Theorem (2.11) we net that if char(k) = 0 then AHA has property (q_1) .

Theorem (2.11) gives significant information also in characteristic p>0.

Indeed together with (1.5), (1.6), (2.8), (2.9) it shows that in arbitrary characteristic PAL f and CLA b have the properties (g_1) , (g_2) , (d_1) , (d_2) . A typical corollary in characteristic p>0 concerns the Frobenius automorphism φ . Indeed if k is the prime field \mathbb{F}_p and A is a bounded local complete K-alnebra (or a polarized finitely presented K-algebra) with K universal such that $A\cong A^{\varphi^n}$ for some $n\geqslant 1$ then A is defined over the alnebraic closure of \mathbb{F}_p .

An example of remarkable functor having property (m) in arbitrary characteristic (cf. [16]) is the functor CRV:B \rightarrow S-CRV(K)= set of isomorphism classes of smooth projective curves over K.

The proof of Theorem (2.11) will be done in Part II of our paper (cf. Corollaries (4.3), (5.3), (6.4), (6.9), (6.10)) using a purely algebraic strategy from our book [5].

(2.12). Note that one could try to prove (δ_1) in a "geometric" way as follows. If C is one of the fibred categories under consideration then each object $A \in C_K$ (K universal) should be viewed intuitively as a "family" over the parameter space Spec(K). Then one could try to replace Spec(K) by a Konvariety Spec (S) (K = E^{A} , K = Sec(1) on which G(A) acts by pirational automorphisms and

then try to use representability of the functor of isomorphisms between objects in $\widetilde{C}_{Spec}(S)$ where \widetilde{C} is an extension of C to the category SCH of schemes (over k). There are serious difficulties with this approach (indeed although one can find by property (d_3) a field definition K_1 for A which is finitely generated over K_0 one cannot find apriori such a K_1 which in addition is stable under g(A) (in fact if K_1/K_0 is transcendental then K_1 is never stable under g(A)!).

Note also that one could try to prove (\mathcal{S}_1) by extending the method of Chow points due to Matsusaka and Shimura. There are difficulties also with this approach. Indeed in their method it is essential the moduli functor takes the form

$$K \longrightarrow \coprod H_{1}(K)/R_{1}(K)$$

with H; certain quasi-projective k-schemes (appearing as locally closed pieces of certain Chow varieties or Hilbert schemes) and R; certain "algebraic" (nonnecessary closed) equivalence relations on H;. But it is not clear (at least apriori) that this holds for the functors under consideration: to see this one would probably need a theory of Chow coordinates (or a "Hilbert scheme") for the corresponding fibred categories (e.g. for complete local algebras or for polarized finitely presented algebras!).

(2.13) Let's close by making some remarks on automorthy phisms in a fibred category C over B. Let KEB^a , AEC_K ; there exists an exact sequence

$$1 \rightarrow Aut_{K}(A) \longrightarrow G(A) \longrightarrow g(A) \longrightarrow 1$$

are pairs $s=(\sigma,v)$ with $\sigma\in g(A)$ and $v:A\to A$:= $C_{\sigma^{-1}}(A)$ an isomorphism in C_K ; the multiplication is defined by

$$(\sigma, v) (\tau, w) = (\sigma \tau, c_{\sigma, \tau} \circ v^{\tau} \circ w)$$

where $v = C_{\tau-1}(v) \in \text{Hom}(A^{\tau}, (A^{\sigma})^{\tau})$ and $C_{\sigma,\tau} = C_{\sigma-1,\tau-1}(A) \in \text{Hom}((A^{\sigma})^{\tau}, A^{\sigma\tau})$. Note that G(A) acts on K via g(A). A key point in our method will be to kill cocycles of G(A) with values in general linear groups $GL_n(K)$.

As an example, if C=CLA and if we view K as a subset of $A \in CLA_K$ then G(A) identifies with the group of all k-automorphisms of A sending K onto K.

The following relation between our setting and Weil's Galois descent worths being noted (although won't be used later). Let $K_{\mathbb{S}}$ be a subfield of K and $A \in C_{K}$. If $K_{\mathbb{S}} \in D(A)$ then one can find a group homomorphism $s: g(K/K_{\mathbb{S}}) \longrightarrow F_{\mathbb{S}}(A)$ which composed with the projection $F_{\mathbb{S}}(A) \longrightarrow F_{\mathbb{S}}(A)$ which composed with the projection $F_{\mathbb{S}}(A) \longrightarrow F_{\mathbb{S}}(A)$ yields the natural inclusion $F_{\mathbb{S}}(K/K_{\mathbb{S}}) = g(A)$. Conversely if such a "section" $F_{\mathbb{S}}(A) = F_{\mathbb{S}}(A)$ where $F_{\mathbb{S}}(A) = F_{\mathbb{S}}(A)$ with $F_{\mathbb{S}}(A) = F_{\mathbb{S}}(A)$ with $F_{\mathbb{S}}(A) = F_{\mathbb{S}}(A)$ we see that we have

for all σ , i.e. the family $\left\{s_{\sigma}; \sigma \in g(K/K_{O})\right\}$ satisfies a condition analogue to Weil's cocycle condition [26]. So if K/K_{O} was a Galois extension, we would get for "reasonable" C's that Weil's discent works and $K_{O} \in D(A)$. In our situation; however, K is universal while K_{O} is the algebraic closure of K^{A} so K/K_{O} is always transcendental; moreover we do not dispose apriori of a "section" S as above. So Weil's Galois descent cannot be applied to deal with property S and S and S are condition analogue to Weil's Galois descent cannot be applied to deal with property S.

PART 1.1: ALGEBRAS OVER SKEW GROUP ALGEBRAS

3. Killing nonabelian cocycles

(3.1) We place ourselves in the setting of [3], section 1. So let G be a group (not assumed to be profinite!); by a G-field (respectively G-group, G-ring,...) we will understand a field (respectively group, ring,...) together with a G-action on it by field (respectively group, ring,...) automorphisms. If K is a G-field and L is a linear algebraic K^G -group then L(K), the group of K-points of L₄ is a G-group.

Recall that if Γ is a G-group one defines the set $Z^1(G,\Gamma)$ of 1-cocycles as the set of all maps $f:G\to\Gamma$ satisfying f(st)=f(s)s(f(t)) for all s,teg. A cocycle f is called a coboundary if there exists $x\in\Gamma$ such that $f(s)=x^{-1}sx$ for all $s\in G$.

(3.2) We make two definitions. An extension E/K of R-fields will be called constrained if the extension E^{C}/K^{C} is algebraic (terminology is inspired from differential algebra [14]); note that if E/K is constrained and K is algebraically closed then $K^{C}=E^{C}$.

Moreover a subgroup G_1 of G_2 is called cofinite if there exists a sequence of subgroups $G_1 = G_2 = \ldots = G_m = G$ such that G_1 is normal of finite index in G_{1+1} for $1 \le i \le m-1$. Clearly the extension G_1 / K^G is then necessarily finite.

- (3.3) THEOREM. Let K be a K-field, L a linear algebraic K^G -group and $f\in Z^1(G,|L(K))$ a cocycle. Then:
- a) There exists a cofinite subaroup K_1 of K and a finitely generated constrained extension of K_1 -fields K_1/K such the image of f via $Z^{\frac{1}{2}}(G,L(K)) \to Z^{\frac{1}{2}}(G_1,L(K_1))$ is a coboundary.

b) If L is geometrically irreducible there exists a finitely generated regular extension of G-fields K_1/K such that the image of f via $Z^1(G,L(K)) \rightarrow Z^1(G,L(K_1))$ is a coboundary.

Proof. Embed L into FL_N for some N and suppose L is defined in $\operatorname{K}^G[X]_d$ by an ideal I where $\operatorname{X}=(X_{i,j})$ and $\operatorname{d=det}(X)$. There is a unique G-action on $\operatorname{K}[X]$ which agrees with our G-action on K and such that $\operatorname{sX}_{i,j} = \sum \operatorname{X}_{i,p}(f(s))_{n,j}$ where $f(s) \in \operatorname{L}(K)$ is viewed as an element in $\operatorname{KL}_N(K)$. Since $\operatorname{sd} = (\operatorname{det} f(s)) \operatorname{d}$ the action above extends to a G-action on $\operatorname{K}[X]_d$; clearly $\operatorname{J} = \operatorname{IK}[X]_d$ is globally G-invariant. To prove b) note that the radical $\operatorname{r}(J)$ of J is a prime ideal in $\operatorname{K}[X]_d$ and clearly is globally G-invariant. Then we put $\operatorname{K}_1 = \operatorname{Q}(\operatorname{K}[X]_d/\operatorname{r}(J))$ and let $\operatorname{x} \in \operatorname{L}(K_1)$ be the K_1 -point of L corresponding to the map $\operatorname{K}^G[X]_d/\operatorname{I} \to \operatorname{K}_1$; clearly $\operatorname{f}(s) = \operatorname{x}^{-1}\operatorname{sx}$ for all $\operatorname{s} \in \operatorname{G}$ and b) is proved.

To prove a) let S be the set of all ideals $[X]_d$ satisfying the following properties:

- 1) J' contains J
- 2) J' is \mathfrak{G}' invariant for some cofinite subgroup \mathfrak{G}' of \mathfrak{G} .

Let J_1 be a maximal member in S and let F_1 be the corresponding cofinite group from condition 2). We claim J_1 is a prime ideal. Indeed let $M = \left\{ P_1, \dots, P_m \right\}$ be the set of primes in $K[X]_d$ minimal over J_1 . Then $F_2 = \ker(F_1 \longrightarrow \operatorname{Aut}(M))$ is still cofinite so $P_1 \in S$ hence by maximality $J_1 = P_1$. Let $K_1 = O(K[X]_d/J_1)$ and $X \in L(K_1)$ as in the proof of b). We are left prove that $K_1 = \int_{F_1}^{F_1} K_1^{F_1} K_2^{F_2} K_1^{F_1} K_1^{F_2} K_1^{F_1} K_1^{F_2} K_1^$

turn is finite over K^G.

Assume there exists a $\in K_1^{n-1}$ transcendental over K and look for a contradiction. By Chevalley's constructibility theorem there exists $g \in K[a]$, $g \neq o$ such that the image of the map $Spec(R_{1}[a])$ Spec(K[a]) contains Spec($K[a]_0$) (where $R_1 = K[X]_d/J_1$ and $R_1[a]$ is the R_1 -subalgebra of K_1 generated by a). We claim there exists a cofinite subgroup \mathfrak{G}_2 of \mathfrak{G} and a \mathfrak{G}_2 -invariant prime ideal $\mathsf{P} \neq \mathsf{O}$ in K[a] not containing g. If K is infinite this is clear. To prove the claim in general note that there exists at least one polynomial $h \in K$ [a] none of whose prime factors h_1, \ldots, h_m in K[a] divides g. Clearly G_1 acts on $K \int a \int and also on the set of ideals$ $F = h_1 K[a], ..., h_m K[a]$. Then the claim follows by taking $G_2 = \frac{1}{2}$ = Ker $(G_1 \longrightarrow Aut(F))$. With P at hand consider the set $E = \{Q_1, \dots, Q_n\}$..., Q_s^2 of minimal primes in the fibre of $Spec(R, [a]) \rightarrow Spec(K[a])$ at P; clearly G_2 acts on R_1 [aland also on E. Then if we let G_3 = -= $Ker(G_2 \rightarrow Aut(E))$ we get that $\Omega = \Omega_1$ is G_3 - invariant hence so will be $Q \cap R_1$, nence so will be the inverse image of $Q \cap R_1$ in $K[X]^7$ which we call J_3 . Now $Q \neq 0$ hence $Q \cap R_1 \neq 0$ (because $Q(R_1) = Q(R_1[a])$) so J_3 strictly contains J_1 . Since \mathfrak{L}_3 is cofinite in \mathfrak{L} this contradicts the maximality of J, and the Theorem is proved.

K-algebra on G; recall that as a K-linear space, K[G] has a basis consisting of the elements of G, while the multiplication is defined by $(c_1s_1)(c_2s_2)=(c_1s_1(c_2))(s_1s_2)$ for all $c_1,c_2\in K$, $s_1,s_2\in G$. We shall be interested in the category of K[G]- modules (note that the (G,K)-spaces from [15] are K[G]- modules while the converse is not true since we do not assume - and this will be important - that the action map $G \rightarrow g(K)$ is injective). If M is a K[G]-module then $s(c_1)=(s_2)(s_1)(s_2)$ for all $s\in G$, $s\in K$, $s\in K$. When we say a K[G]- module is finite dimensional we mean it has finite dimension over K. The field K is a $s\in G$ - necule in a natural way.

For any K[G] - module M put $M^G = \{x \in M; x \in X \text{ for all } x \in G\};$ M^G is a K^G -linear space and we have a natural injective map

$$K \otimes K^{G}(M^{G}) \longrightarrow M, \qquad c \otimes X \longmapsto cX$$

We will often identify $K \otimes_{K} (M^G)$ with the image of the above map. If this map is surjective we say that M is a split K[G]- module; clearly M is split if and only if it is has a K-basis contained in M^G . Moreover one easily checks that any sub-K[G]- module of a split K[G]- module is split (use an argument similar to that in [5] p.55). If K_1/K is an extension of G-fields and if M is a K[G]- module then $K_1 \otimes_K M$ has a natural structure of $K_1[G]$ - module defined by $S(C \otimes_K) = SC \otimes_K S$

(3.5) A useful remark is that if M is a split K[G]-module, G_1 is a subgroup of G and K_1/K is an extension of G_1 -fields then the following hold:

- 1) $K_1 \otimes_K M$ is a split $K_1 \begin{bmatrix} G_1 \end{bmatrix}$ module and
- 2) the natural map

$$f: (K_1^{G_1}) \otimes_{K_G} (M^G) \longrightarrow (K_1 \otimes_{K_M})^{G_1}$$

is an isomorphism.

The first assertion is clear since $K_1 \otimes_K M$ has a K_1 -basis consisting of G-invariant elements in M. To prove the second assertion it is sufficient to check that f becomes an isomorphism after tensorization with K_1 over $K_1^{G_1}$. But after tensorization both the source and the target of f naturally identify with $K_1 \otimes_K M$ so we are done.

Now exactly as in [15] our Theorem (3.3) on killing :

ses" so we get.

- (3.6) COROLLARY. Let K be a G-field, Ma K $\lceil G \rceil$ module of finite dimension. Then:
- a) There exist a cofinite subgroup κ_1 of κ and a finitely generated constrained extension κ_1/κ of κ_1 fields such that $\kappa_1 \otimes \kappa$ M is a split $\kappa_1 \kappa_1 \kappa_1$ module.
- b) There exists a finitely generated regular extension K_1/K of G-fields such that $K_1 \otimes_K M$ is a split $K_1[G]$ -module.

4. Polarized K[G]- algebras

(4.1) Let K be a G-field. Following [19] p.952, by a K[G]- a secret = K-algebra A which is also a K[G]- module such that the multiplication map $A \otimes_K A \to A$ and the unit K $\to A$ (if there is any) are K[G]- module maps (here $A \otimes_K A := = K[G]-$ module via $s(a_1 \otimes a_2)=sa_1 \otimes sa_2$ for $s \in G_1$, $a_1,a_2 \in A$). By a polarized K[G]- algebra we will mean a polarized K-algebra A which is also a K[G]- algebra such that P_A is a K[G]- submodule of A.

Following [19] p.957 we say that the (polarized) K[G]-algebra A is split if there is an isomorphism of (polarized) K[G]-algebras $A \cong K \otimes K^G$ (A^O) for some (polarized) K^G -algebra A^O where $K \otimes K^G$ (A^O) is given the structure of $K \otimes K^G$ -algebra defined by $K \otimes$

(4.2) THEOREM. Let A be a polarized K[G]- algebra. Then:

1) There exists cofinite subgroup κ_1 of κ_1 and a finite-ly generated constrained extension κ_1/κ of κ_1 -fields such that $\kappa_1 \otimes_K A$ is a split polarized $\kappa_1 \lceil \kappa_1 \rceil$ - algebra.

There exists a finitely generated regular extension of G-fields K_1/K such that $K_1 \otimes_{K} A$ is a split polarized $K_1[G]$ - algebra.

Proof. Let $\gamma: K < P > \to A$ be the natural surjection, $P=P_A$ and $J=Ker(\gamma)$. To prove assertion 1), by part a) in (3.6) there exists a cofinite subgroup G_1 of G and a finitely generated constrained extension of G_1 -fields K_1/K such that $P_1:=K_1 \otimes_K P$ is a split $K_1/G_1/F_1$ -module. Consequently $K_1/F_1>$ is a split $K_1/G_1/F_1$ -algebra. Since $K_1 \otimes_K F$ is a $K_1/G_1/F_1$ -submodule of $K_1/F_1>$ it is split; this immediately implies that $K_1 \otimes_K F$ is a split polarized $K_1/F_1/F_1$ -algebra. The proof of 2) is similar using part b) in (3.3) instead of part a).

(4.3) COROLLARY. The functor PAL has properties $(\hat{c_1})$ and $(\hat{s_2})$.

Proof. Any polarized K-algebra A has a structure of polarized K [G]-algebra with G=G(A, PAL) (see (2.13)): for any $S=(G,v)\in G$, $G\in G(A, PAL)$, $V:A\longrightarrow A^G$ and any $a\in A$ we put $S=P_G(V(a))$ where $P_G:G\otimes P_A:A^G=K\otimes F_A$ (where K is K itself viewed as a K-algebra via $G^{-1}:K\longrightarrow K$). We conclude by (4.2).

5. Complete local K[XI][G] - algebras

(5.1) Let K be a K-field. By a complete local K[G]- algebra we mean a complete local K-algebra which is also a K[G]- algebra. If $X=(X_1,\ldots,X_N)$ by a complete local K[X][G]- algebra we mean a complete local K[G]- algebra together with a local algebra homomorphism $u:K[X] \longrightarrow A$ such that $u(X_1) \in A^G$ for $1 \le i \le N$.

Let A be a complete local K[X][G] - algebra; is called split if there is a K[X][A] - algebra isomorphism $A \cong K \otimes K[A]$ with K[X][A] a complete local K[X][A] - algebra such that for the induced K[A][A] - algebra structure on $K \otimes K[A][A]$ we have $S(C \otimes X) = SC \otimes X$ for all $S \in G$, $C \in K$, $X \in A^O$.

(5.2) THEOREM. Let A be complete local K[X][G] - algebra. Then:

- 1) There exists a field extension \widetilde{K}/K such that $D(\widetilde{K} \bigotimes^{\Lambda}_{K}A$, CLS) contains an algebraic extension of K^{G} .
- 2) There exists a countably generated regular extension of G-fields \widetilde{K}/K such that $\widetilde{K} \overset{\wedge}{\bigotimes}_{K} A$ is a split complete local K[X][G]-algebra.

Proof. We shall prove 1) and 2) simultaneously referring to them as to case 1) and 2). For all $n \ge 2$, $A_n = A/M^n$ is a finite dimensional K = G module (M = M(A)). By (3.6) one can construct inductively a sequence $G = G_1 = G_2 = G_3 = 0$. of subgroups of G and a sequence $K = K_1 = K_2 = K_3 = 0$. of fields such that for all $n \ge 2$ the following conditions are satisfied:

- a) K_n is a G_n -field
- b) K_n/K_{n-1} is a finitely generated extension of G_n fields which is constrained in case 1) and regular in case 2).
- and $G_{n}=G_{n-1}$ in case 2).
- d) $K_n \otimes_K A_n$ is asplit $K_n \llbracket G_n \rrbracket$ module (call it B_n). Now put

$$K_{n}=K_{n}^{G_{n}}$$
, $C_{n}=B_{n}^{G_{n}}$, $\widetilde{K}=\bigcup K_{n}$, $\widetilde{k}=\bigcup k_{n}$, $A_{n}^{G}=\widetilde{k}\otimes k_{n}^{G}C_{n}$

Note that k/K^G is algebraic in case 1) and regular in case 2);

moreover in case 2) $\widetilde{k}=\widetilde{K}^G$. Clearly A_n^O is a \widetilde{k} -subalgebra of $\widetilde{K} \bigotimes_{K} A_n$ and we have $\widetilde{K} \bigotimes_{K} (A_n^O) = \widetilde{K} \bigotimes_{K} A_n$. Since the natural maps $f_n : B_{n+1} \longrightarrow K_{n+1} \bigotimes_{K} B_n$ are maps of $K_{n+1} [G_{n+1}]$ - modules we get by (3.5):

$$f_n(C_{n+1}) \subset (K_{n+1} \otimes_{K_n} B_n)^{G_{n+1}} = k_{n+1} \otimes_{K_n} C_n$$

Consequently the maps $\widetilde{K} \otimes_K A_{n+1} \to \widetilde{K} \otimes_K A_n$ send A_{n+1}^O onto A_n^O . We claim that with these data one can construct a complete local $\widetilde{K}[\widetilde{[X]}]$ - algebra A^O and a $\widetilde{K}[\widetilde{[X]}]$ - isomorphism $f = \widetilde{K} \otimes_{\widetilde{K}} A^O \to \widetilde{K} \otimes_{K} A^O$. Moreover we may assume in case 2) that the G-action induced via f on $\widetilde{K} \otimes_{\widetilde{K}} A^O$ is the "split" action; clearly this will close the proof of the theorem.

Now the claim above can be proved by using an argument from [5] p.80; we reproduce it for convenience. If s is the embedding dimension of A and Y=(Y,...,Y) are indeterminates one can find surjective maps $p_n: k[Y] \to A_n^0$ which agree with the projections $A_{n+1}^0 \to A_n^0$. Upon letting $J_n = \ker(p_n)$ we have K-isomorphisms

which are compatible with the projections obtained by "passing from n+1 to n". Put $J_0 = \bigcap_{n \to \infty} J_n$ and $A^0 = k \left[\frac{1}{L} Y! \right] / J_0$. We have isomorphisms

$$\widetilde{K} \stackrel{\wedge}{\otimes} \widetilde{\kappa} A^{\circ} \simeq \widetilde{K}[Y] / J_{\circ} \widetilde{K}[Y] \stackrel{\sim}{\longrightarrow} \widetilde{K}[Y] / \bigwedge (J_{n} \widetilde{K}[Y]) \stackrel{\partial}{\longrightarrow}$$

$$\stackrel{\beta}{\longrightarrow} \lim (\widetilde{K}[Y] / J_{n} \widetilde{K}[Y] \simeq \lim (\widetilde{K} \otimes KA_{n}) = \widetilde{K} \stackrel{\wedge}{\otimes} KA$$

Indeed to see that \ll is an isomorphism we use the fact that $\bigwedge (J_n \widetilde{K[[Y]]}) = J_0 \widetilde{K[[Y]]}$ which is proved as follows. Upon letting $I_n = J_n/J_0 = C = \widetilde{k[[Y]]}/J_0$ and $B = \widetilde{K[[Y]]}/J_0 \widetilde{K[[Y]]}$ we are reduced to proving that for any extension C=B of local noetherian rings with C complete and for any sequence of ideals $(\underline{I}_n)_{n \gg 1}$ in C with

 $\bigcap_{n=0}^{\infty}$ we have $\bigcap_{n=0}^{\infty} (I_n B) = 0$. Now by [18] p.103 there is a function $m: \mathbb{N} \to \mathbb{N}$ such that $I_{m(n)} \in (M(\mathbb{C}))^n$ for all $n \geqslant 1$ hence $\bigcap_{n=0}^{\infty} (I_m(n)^n B) = 0$ and we are done. To check that $\bigcap_{n=0}^{\infty} (M(B))^n = 0$ and we are done. To check that $\bigcap_{n=0}^{\infty} (M(B))^n = 0$ and we are done. To check that $\bigcap_{n=0}^{\infty} (M(B))^n = 0$ and we are done. To check that $\bigcap_{n=0}^{\infty} (M(B))^n = 0$ and we are done. To check that $\bigcap_{n=0}^{\infty} (M(B))^n = 0$ and we are done in the complete local ring is complete in any separated linear topology on it.

On the other hand if we denote by x_{in} the image of X_{i} in A_{n} then $x_{in} \in A_{n}^{\circ}$ hence we get \widehat{k} -algebra homomorphisms $u_{n}:\widehat{k[XI]} \rightarrow \widehat{k[YI]}/J_{n}$ which agree/with the projections $\widehat{k[YI]}/J_{n+1} \rightarrow \widehat{k[YI]}/J_{n}$. Since $\widehat{k[YI]}/J_{o}=\lim_{k \to \infty}\widehat{k[YI]}/J_{n}$, u_{n} yeld a \widehat{k} -algebra map $\widehat{k[XI]} \rightarrow A^{\circ}$. It is easy to see that the \widehat{k} -isomorphism $\widehat{k} \otimes_{\widehat{k}} A^{\circ} \rightarrow \widehat{k} \otimes_{\widehat{k}} A$ constructed above is in fact a k[XI]- algebra map and our Theorem is proved.

(5.3) COROLLARY. The functor CLS has properties (δ_1) and (δ_2) .

Proof. Any local complete K[X]- algebra A has a natural structure of K[X][G]- algebra with G=G(A, CLS) (exactly as in (4.3) and we conclude by (5.2).

6. Hopf K[G] - algebras

(6.1) Throughout this section we shall often identify an affine Hopf K-algebra A with the linear algebraic K-group L=Spec(A) and we write $A=\Gamma(L)$; moreover if K is algebraically closed we shall sometimes use the letter L to denote also the group L(K) of K-points of L.

Following [19] p.952 by a Hopf K[G]- algebra we mean a Hopf K-algebra [13] [15] which is also a K[G]- algebra such that the comultiplication $A \to A \otimes_K A$ and the counit $A \to K$ are K[G]-module mans. A Hopf K[G]- algebra A is called split if there is

(6.2) THEOREM. Let K be algebraically closed of characteristic zero and let A be an affine Hopf K[G]- algebra. Then D(A, AHA) contains an algebraic extension of K $^{\rm G}$.

The key point in proving (6.2) is the following:

- (6.3) THEOREM. Let K/K_O be an extension of algebraically closed fields of characteristic zero and L a linear algebraic K-group with unipotent radical $U=R_{tL}(L)$. Then $K_O \in D(L, AHA)$ if and only if $K_O \in D(Lie(U), PAL)$, where Lie(U) is the Lie algebra of U viewed as a polarized K-algebra via $P_{Lie(U)} = Lie(U)$.
- (6.4) COROLLARY. If ther(k)=0 the functor AHA has property (\mathcal{E}_{j}) .
- (6.5). Proof of Theorem (6.3). If L=L $^{\circ}$ \otimes K with L $^{\circ}$ a linear algebraic K $_{\circ}$ -group then U=U $^{\circ}$ \otimes K where U $^{\circ}$ is the unipotent radical of U hence K $_{\circ}$ is a field of definition for U, in particular for Lie(U). Conversely, if K $_{\circ}$ is a field of definition for Lie(U) then so it will be for U because U is isomorphic as an affine variety with the spectrum of the symmetric algebra on Lie(U), the isomorphism being given by "exp" while the multiplication on U is defined by the Campbell-Hausdorff formula which involves only rational coefficients [12] p.228. So we may write U \cong U $^{\circ}$ \otimes K for some unipotent K $_{\circ}$ -group U $^{\circ}$. Now by [12], p.117 L is a semidirect product of U with some linearly reductive subgroup P=L. P is then reductive and in particular P=P $^{\circ}$ \otimes K for

some reductive K-group $P^{\circ}[7]$. By $\sqrt{3}$ the group Aut(U) of algebraic group automorphisms of U is an algebraic K-group; moreover we must have $\operatorname{Aut}(U) = \operatorname{Aut}(U^{\circ}) \otimes \operatorname{K}_{\circ} K$. Furthermore the group homomorphism $\rho: P \to Aut(U)$ defined by $\rho(p)u=p^{-1}up$ ($p \in P$, $u \in U$) is also algebraic. We claim there is a K-point σ of Aut(U) and a morphism of algebraic K_o-groups $\rho^{\circ}: P^{\circ} \longrightarrow Aut(U^{\circ})$ such that $\rho^{\circ} \otimes 1_{K} = Inn_{\circ} \rho$ where Inn \in Aut (Aut (U)) is defined by Inn $(\tau) = \sigma^{-1} \circ \tau \circ \sigma$. Indeed since P is linearly reductive, by [8] p.194 we have in particular H (P, Lie(Aut(U))=0 (with P acting on Lie(Aut(U)) via ρ and the adjoint representation of Aut(U)). By $\lceil 9 \rceil p.116$ the above cohomology group identifies with the space of "first order deformations" of ρ modulo the "first order deformations arrising from infinitesimal inner automorphisms of Aut(U)". Now the existence of ρ° and σ follows for instance from [67 (2.11) plus an obvious specialisation argumest. With ρ^0 and σ at hand we may define an isomorphism of algebraic K-groups

by the formula $\varphi(u,p)=(\sigma^{-1}(u),p)$ where $U\times_{p}P$ is set theoretically $U\times_{p}P$ with multiplication given by $(u_{1},p_{1})(u_{2},p_{2})=$ $=((p(p_{2})u_{1})u_{2},p_{1}p_{2})$ and $U\times_{p}P$ is defined similarly with $r=p^{0}\otimes 1_{K}$ instead of p. But $U\times_{p}P=(U^{0}\times_{p}P^{0})\otimes_{K}K$ and Theorem (6.3) is proved.

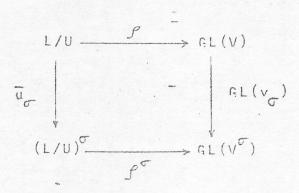

(6.6) Proof of Theorem (6.2). A is the coordinate Hopf algebra of an algebraic K-group L. Let U be the unipotent radical of L and J the defining prime ideal of U in A. We claim that s(J)=J for all $s\in G$. Indeed upon letting G to be the image of s in g(K) it is sufficient to prove that the natural map $p_{G}: L \to L$ given in some matrix representation by $(x_{i,j}) \mapsto (Gx_{i,j})$ carries

the unipotent radical of L onto the unipotent radical of L (here of course L = Spec(A). But this follows from the fact that the map p_{σ} is an abstract group isomorphism. (of course not an algebraic K-group isomorphism!), it takes Zariski closed sets into Zariski closed sets and takes unipotent matrices into unipotent matrices, so our claim follows. We deduce that the coordinate Hopf algebra B=A/J of U has an induced structure of Hopf K[G]— algebra. Then one easily checks that Lie(U) also has a (naturally induced) structure of Lie(K[G])— algebra (use for instance the K[G]— algebra structure on the convolution algebra $(B^* = Hom_K(B, K), *)$ and the description of Lie(U) as a Lie subalgebra of the Lie algebra $(B^*, [,])$, [F, g] = f * g - g * f of [13]). Now if K_0 is the algebraic closure of K^G in K by (4.2) and property (s) we have $K_0 \in D(Lie(U), PAL)$ hence by (6.3) $K_0 \in D(L, AHA)$ and we are done.

(6.7) Let's discuss rigidified and pure affine Hopf algebras. Suppose K is algebraically closed of characteristic zero, A is an affine Hopf K[G]- algebra, L=Spec(A), U=R_U(L). The arguments in (6.6) show that U and hence also L/U have on their coordinate Hopf algebras natural structures of Hopf K[G]- algebras. Let now B be an affine Hopf K[G]- algebra; by a K[G]- representation V of B (or of Spec(B)) we mean a finite dimensional K[G]- module V together with a Hopf K[G]- algebra map $\Gamma(GL(V)) \rightarrow B$; V is called faithfull if the above map is surjective. Here $\Gamma(GL(V))$ has the structure of Hopf K[G]-algebra induced by that of V via the following formulae: if e_1, \ldots, e_n is a K-basis of V, e is the column vector with entries e_1, \ldots, e_n and se=a(s)e where se=a(s)e where se=a(s)e and if fe=a(s)e is a matrix of indeterminates which are coordinates on fe=a(s)e then we put fe=a(s)e (product of matrices).

- (6.8) THEOREM. Let K be algebraically closed of characteristic zero, A an affine Hopf K $\llbracket G \rrbracket$ algebra, L=Spec(A), U=R $_{
 m U}$ (L) and let V be a faithful K $\llbracket G \rrbracket$ representation of L/U. Assume there is a maximal reductive subgroup P of L whose ideal in A is G-globally invariant. Then:
- 1) There exists a cofinite subgroup \widetilde{G} of G and a finitely generated constrained extension \widetilde{K}/K of \widetilde{G} -fields such that $\widetilde{K} \otimes_{K} A$ and $\widetilde{K} \otimes_{K} \Gamma(L/U)$ are split Hopf K[G]- algebras and $\widetilde{K} \otimes_{K} V$ is a split K[G]- module.
- 2) There exists a finitely generated regular extension of G fields \widetilde{K}/K such that $\widetilde{K} \otimes_{K} A$, $\widetilde{K} \otimes_{K} \Gamma(L/U)$ are split Hopf K[G]-algebras and $\widetilde{K} \otimes_{K} V$ is a split K[G]-module.
- (6.9) COROLLARY. If char(k)=0, AHA has properties (S₁) and (S₂).

Proof. Let $L \subseteq AHA_K$, $U=R_L(L)$ and $g:L/U \longrightarrow GL(V)$ a rigidification. Let H be the group of all triples $s=(\sigma, u_\sigma, v_\sigma)$ where $\sigma \in g(K)$, $u_\sigma:L \longrightarrow L^\sigma$ and $v:V \longrightarrow V^\sigma$ are isomorphisms and the following diagram is commutative:

where \overline{u}_{G} is deduced from u_{G} while $GL(v_{G})(x)=v_{G}^{-1}xv_{G}$. Write $L=Ux_{G}$ P for some $Q:P\longrightarrow Aut(U)$ and let G be the subgroup of H consisting of all (G,u_{G},v_{G}) for which $u_{G}(P)=P$. By (6.8) we shall be done if we prove that G and H have the same image in g(K). Now if $(G,u_{G},v_{G})\in H$, by the conjugacy of maximal reductive

groups in $L^{\sigma}([12] p.117)$ there exists a K-point xeU such that $x^{-1}(u_{\sigma}(P))x=P^{\sigma}$. Put $w_{\sigma}=Int_{x^{\sigma}u_{\sigma}}$. Then $w_{\sigma}=\overline{u_{\sigma}}$ and consequently $(\sigma,w_{\sigma},v_{\sigma})\in G$ which ends our proof.

(6.10) COROLLARY. If char(k)=0, AHA^p has property (\mathcal{S}_2) .

Proof. Let K be algebraically closed, $A \in AHA_K^P$, L = Spec(A). $U = R_{u}(L)$, P = L/U. By (6.9) and the fact that $k \in D(P, AHA)$ [7] it is sufficient to construct a faithful representation $p:P \to GL(V)$ such that for any $f \in Aut(P)$ there exists $f \in GL(V)$ such that $f \in F = Int_{\psi} \circ f \circ F$. Start with any faithful representation $f \in P \to GL(W)$, select a (finite) set $f \in T_1, \dots, f_N \in Aut(P)$ of representatives modulo $f \in F$ and let $f \in F$ be the representations of $f \in F$ defined by the composition $f \in F$ and let $f \in F$ be the representations of $f \in F$ defined by the composition $f \in F$ be the representations of $f \in F$ defined by the composition $f \in F$ be the representations of $f \in F$ defined by the composition $f \in F$ be the representations of $f \in F$ defined by the composition $f \in F$ be the representations of $f \in F$ defined by the composition $f \in F$ be the representations of $f \in F$ defined by the composition $f \in F$ be the representation of $f \in F$ be the representation of

 $V=W_1 \oplus W_2 \oplus \ldots \oplus W_N$ (as representations)

(6.11). Proof of (6.8). We prove 1) and 2) simultaneously. Once again write L=U $_{\infty}$ P with $_{\infty}$:P $_{\longrightarrow}$ Aut (U) and let $_{\mathcal{P}}$:L/U $_{\longrightarrow}$ GL(V) define our representation. Composing with the isomorphism P $_{\longrightarrow}$ L $_{\longrightarrow}$ L/U we get a representation $_{\Xi}$:P $_{\longrightarrow}$ GL(V). By (3.6) there exist finitely generated extensions $K=K_1=K_2$ and subgroups $G=G_1=G_2$ such that K_1/K is a G_1 -extension, K_2/K_1 is a G_2 -extension, K_1/K_1 is a split K_1/K_1 module, K_2/K_1 is a split K_1/K_1 module, K_2/K_1 is a split K_1/K_1 module (hence a split Lie K_2/K_2 algebra) and moreover

- a) in case 1) $\rm G_1, \rm G_2$ are cofinite in $\rm G$ and $\rm K_1/\rm K, K_2/\rm K_1$ are constrained,
- b) in case 2) $R = R_1 = R_2$ and R_1/R , R_2/R_1 are regular. We claim that $\Gamma(\operatorname{Aut}(U))$ has a natural structure of Hopf R[R] algebra induced by that of $\Gamma(U)$; this can be seen by taking the embedding $\operatorname{Aut}(U) \xrightarrow{e_{A}D^{+}} \operatorname{Aut}(\operatorname{Lie}(U)) \to \operatorname{RL}(\operatorname{Lie}(U))$. Moreover the splitting of $R = \mathbb{Q}_p$. Lie(U) as a Lie R_2/R_1 algebra yields (via the

exponential map) a splitting

$$K_2 \otimes_K U \simeq K_2 \otimes_{(K_2)} G_2$$
 (U°)

of Hopf $K_2[G_2]$ - algebras, hence a splitting

$$K_2 \otimes K^{Aut(U) \simeq K_2} \otimes K_2 \otimes K_2$$
 (Aut(U°))

as Hopf $K_2 [G_2]$ - algebras.

We claim that $\alpha: P \to \operatorname{Aut}(U)$ yields a map of Hopf K[G]—algebras between the corresponding coordinate algebras. This can be seen as follows: the action of G on $A = \Gamma(L) = \Gamma(U \times_{\alpha} P)$ yields for any $s \in G$ a K-isomorphism

$$\Psi = \Psi_{S} : U \times_{\alpha} P \longrightarrow U^{\tau}_{X} P^{\tau}$$

where $\sigma=s/K$ such that $\varphi(U)=U^T$, $\varphi(P)=P^T$ (the latter follows from our condition that the ideal of P in A is G-invariant). For any uEU, pEP we have

$$\begin{split} & \varphi((u,1)(1,p)) = \varphi(u,1) \, \varphi(1,p) = (\varphi(u),1) \, (1,\varphi(p)) = \\ & = (\alpha^{\sigma}(\varphi(p)) \, \varphi(u) \, , \varphi(p)) = \varphi(\alpha(p) \, u,p) = (\varphi(\alpha(p) \, u) \, , \varphi(p)) \end{split}$$

This gives the commutativity of the diagram

$$\begin{array}{ccc}
P & \longrightarrow & Aut(U) \\
\downarrow & & \downarrow & C_{\psi} \\
P & \longrightarrow & Aut(U^{\sigma})
\end{array}$$

where $C_{\varphi}(f) = \varphi \circ f \circ \varphi^{-1}$ hence our claim is proved.

To conclude note that we have two Hopf $\mathrm{K}_2[\mathrm{G}_2]$ - algebra maps:

$$\varepsilon^*: \Gamma(\operatorname{GL}(\mathsf{K}_2 \otimes_{\mathsf{K}} \mathsf{V})) \longrightarrow \Gamma(\mathsf{K}_2 \otimes_{\mathsf{K}} \mathsf{P})$$

$$\alpha^*: \Gamma(\mathsf{K}_2 \otimes_{\mathsf{K}} \operatorname{Aut}(\mathsf{U})) \longrightarrow \Gamma(\mathsf{K}_2 \otimes_{\mathsf{K}} \mathsf{P})$$

Since $\Gamma(\operatorname{GL}(K_2 \times_K V))$ is split, $\ker(\varepsilon^*)$ is split; since ε^* is surjective, $\Gamma(K_2 \otimes_K P)$ is split. Since ε^* and α^* take G_2 -invariants into G_2 -invariants we get $E=K_2 \otimes_K (\varepsilon^0)$, $\alpha=K_2 \otimes_K (\varepsilon^0)$ where $K_0=K_2^{G_2}$ and

$$E^{\circ}: P^{\circ} \longrightarrow GL(V^{\circ}), P^{\circ} \text{ a reductive } K_{\circ}\text{-group}$$

$$\alpha^{\circ}: P^{\circ} \longrightarrow Aut(U^{\circ})$$

which closes our proof.

7. Remarks and open questions

(7.1) Let K be algebraically closed (of characteristic zero, to fix ideas) and A an affine K[G]- algebra (respectively an affine Hopf K[G]- algebra). One could ask whether there exist a cofinite subgroup G_1 of G and an extension K_1/K of G_1 -fields such that $K_1 \otimes_K A$ is a split $K_1 G_1$ - algebra (respectively a split Hopf $K_1 G_1$ - algebra). By our theory this is easily seen to be true if A has non negative Kodaira dimension (respectively if A is pure). But it fails in general. Here is an example. Let $A = k [t_1, t_2, t_1^{-1}, t_2^{-1}] = \Gamma(G_m \times G_m)$ and let G_1 be the infinite cyclic group with generator G_1 and G_2 is a subgroup with generator G_1 .

$$st_1 = t_1 t_2^m$$
, $st_2 = t_2$

(7.2) There are very natural "moduli functors" from B to S which are not coursely representable. We give here an example. For any field K let ALG denote the category of K-algebras; for any field extension $K \rightarrow K/$, the base change functors $ALG_K \rightarrow ALG_{K'}$ $A \mapsto K' \otimes I$ A yield a fibred category and a moduli functor ALG; moreover denote by ALG the subfunctor of ALG (fully embedded into ALG) of commutative associative unitary algebras. Since ALG, ALG have no finitness properties it is not reasonable to expect that they have property (m); but one might still hope that they are coarsely reprsentable (by some birational set not necessarily of finitely generated type). The fact is that neither ALG nor ALG are coursely representable. Indeed coarse representability implies property (d_1) ; on the other hand we can show that ALG (and hence also ALG) does not have this property. Just take . k to be arbitrary, KEB^U arbitrary, A=K(T)=field rational functions in the indeterminate T and $\xi \in ALG^{c}(K)$ be the isomorphism class of A. Clearly $K^{\frac{\xi}{k}}$ is algebraic. On the other hand if $E \in D(\xi)$ and ${\bf A_E}$ is an E-algebra such that ${\bf A}{\simeq}{\bf K} \otimes {\bf E}{\bf A_E}$ then ${\bf K} \otimes {\bf E}{\bf A_E}$ is a field which may happen only if K/E is algebraic hence only if E/K is transcendental; consequently ALG c does not have property (d $_{1}$).

- (7.3) Here are some questions for which we would like to have a positive answer.
- 1) Do AFF or AHA have property (m) (at least if char(k)= =0)?
- 2) Do the functors in Theorem (2.10) have property (m) in characteristic p>0?
- 3) Are CLA, COH, LFS coursely representable (by a birational set not necessarily of finitely generated type)?

Concerning 1) it would suffice for AFF to have properties (δ_1) , (δ_2) and for AHA to have property (δ_2) .

Concerning 2) what would be missing for PAL $^{\rm b}$ and CLA $^{\rm b}$ is property (g3).

Concerning 3) note that CLA satisfies (d_1) and (d_2) (unlike ALG or ALG , for instance).
